

Kentish Council

PUBLIC NOTICE

APPLICATION FOR DEVELOPMENT APPROVAL

An application for development approval has been made which may affect you.

Details about the application – K-DA070/2023

Address of the land

What use or development is proposed in the application

134 Cables Road SHEFFIELD

Resource Development – proposed DAIRY SHED

Date of notice

13 December 2023

The application and supporting documents are open for public inspection on Council's website at <u>www.kentish.tas.gov.au</u> or at the Council Offices, 69 High Street, Sheffield during the following office hours:-Monday to Friday, 8.00 a.m to 4.30 p.m.

Any person may lodge a representation on the proposed use or development.

Your representation must: - be <u>received</u> within 14 days of the date of this notice;

- be in writing;
- be addressed to: The General Manager,

Kentish Council,

P.O. Box 63, Sheffield 7306; or email

council@kentish.tas.gov.au

- and include:

the reasons for your representation; and the address of the land.

1 Statement of intent

Effluent Management Plans must be developed specifically for an individual farm. Likewise, an Effluent Management Plan cannot be developed without considering changes that are likely to occur in the future. This Plan documents the design and planning undertaken for the proposed new dairy at Sheffield.

Please report any discrepancy, omission or inaccuracy in this documentation of the farm's specific variables. Without such a claim for correction, this report shall be taken as an accurate description of the farm and operational parameters at the date of the farm visits for the purposes of effluent system design.

Please also note that this Plan is only valid as long as those parameters remain unchanged. Whenever changes occur, this Plan should be reviewed by an accredited dairy effluent designer.

2 Introduction

This Plan was developed to design the effluent management system for the proposed Cables dairy at 134 Cables Rd, Sheffield. It has been prepared to ensure the compliance with the *Farm Dairy Premises Effluent Management Code of Practice 2010.*

The Code lists three outcomes that dairy effluent management systems must comply with. These outcomes are;

- 1. Dairy premises effluent must not leave the farm boundaries or enter surface water or groundwater, unless treated and discharged in a manner approved by the relevant authorities.
- 2. There must be an appropriately designed and operated system for the responsible management of dairy premises effluent.
- 3. Spray irrigation or distribution of dairy premises effluent is carried out in an environmentally sound manner.

3 Property Background

The dairy farm is located at 134 Cables Rd, Sheffield. It is approx. 170 ha in area, much of which is irrigated.

Figure 1 Aerial image of the location, with the blue shading indicating the extent of the farm

Figure 2 Proposed layout of the dairy shed and effluent system

The farm details are provided in Table 1 while the specific dairy details are provided in Table 2.

Table 1 Farm details

Catchment area impervious	572 m ²
Catchment area pervious	-

Figure 3 Herd details except from the effluent toolkit

The property is undulating, with elevations ranging from 230m to 305m AHD.

4 Water usage

An accurate estimate of the wastewater volume entering the effluent system is important in order to correctly size treatment and storage volumes.

4.1 Dairy water usage

As the dairy is not yet operational, an estimated of 15,000L per day has been used. This aligns to the 75th percentile for existing dairy farms from the Effluent Toolkit and thus is a conservative estimate.

The yard wash water will be recycled from the green water pond, reducing the fresh water usage to approx. 7,500L per day.

4.2 Stormwater input

There is an impervious stormwater catchment area of 572 m² consisting of the concrete yards and other unroofed concreted areas that drain to the effluent system.

5 Environmental variables

5.1 Soils

Majority of the farm is of Red ferrosol in nature.

They have the following characteristics

• These soils display a gradual increase in texture (clay content) with depth. Surface soils are often clay loams that grade into light clays in the subsoil.

• These soils are relatively high in free iron oxide - giving them the distinctive red colour. The high iron levels can 'lock up' applied phosphorus but also contribute to this soil's well-developed soil structure. The structure is usually very fine (usually polyhedral), usually with smooth and often shiny faces. This well developed structure provides plenty of opportunity for water, air and root movement.

• They are usually moderately to strongly acid throughout - a product of their good porosity, high rainfall and long periods of leaching.

• Although these soils are considered to be well structured and attractive for agriculture, they can degrade under intensive cropping from erosion and compaction and may also suffer from acidification.

5.2 Climate

The following data is taken from SILO (<u>https://www.longpaddock.qld.gov.au/silo/point-data/</u>) which provides interpolated climate data from Bureau of Meteorology recording stations.

The site experiences a 90th percentile rainfall (MR^{90}_{adj}) of 1,381 mm per annum and crop-adjusted 10th percentile evapotranspiration (ETc^{10}_{adj}) of 832 mm per year. This is summarised in Table 3. The toolkit recommends that effluent is stored for any month where MR^{90}_{adj} exceeds ETc^{10}_{adj} by 10mm, indicating a higher risk of effluent irrigation runoff to surface waters.

Unusually, the monthly deficit between MR^{90}_{adj} and ETc^{10}_{adj} occurs in two separate periods of the year, December and March to October. Given that the December deficit is only 1mm and that there would be ample opportunity to irrigate in this month, it is not included in the storage period.

Additionally March and November are recommended storage months as the deficit, while positive, is less than 10mm. Again, common sense dictates that there will be opportunities for irrigation in these shoulder months so these periods are also excluded from the storage period.

This results in a 7-month storage window being applied, from April to October. The effluent system will be designed to have adequate volume to store all effluent produced during this period.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total

 Table 3 90th percentile adjusted rainfall, 10th percentile adjusted evapotranspiration and resultant soil moisture deficit by month

5.3 Buffer distances from sensitive receptors

The Farm Dairy Premises Effluent Management Code of Practice May 2010 is the most recent code of practice and replaces the Code of Practice – Managing Dairy Farm Effluent in Tasmania 1997. The previous Code specified specific buffer distances for effluent storage and application. These are no longer relevant under the new code, which simplifies the requirements of an effluent system to meet the three outcomes presented in section 2.

The site and all adjacent properties are zoned rural resource, as such there is no residential zoned property in proximity to the farm.

Sensitive receptors in in proximity to the effluent system and effluent irrigation area include

- Residences near the farm, including:
 - 79 Cables Rd, south of the farm
 - o 151 Cables Rd, south west of the farm
 - Lot 2 Hughes Rd, north east of the farm
 - o 81 Hamptons Rd, north west of the farm
- The Don River, running south through the middle of the farm
- Unnamed drainage line running east to the Don River, above the dairy shed site.

The effluent ponds are 300m from the nearest residence and 40m from the Don River. The ponds will be constructed with adequate clay lining on the base and walls to prevent loss of effluent through the pond to the environment. The ponds have been sized to provide adequate winter storage, ensuring that effluent generated during the periods when irrigation reuse cannot occur can be stored and not discharged in an

uncontrolled manner.

The irrigation reuse areas will maintain a 20 m buffer to property boundaries and waterways and at least 100m buffer to neighbouring residences. As effluent irrigation will only occur in dry periods, the risk of runoff from irrigation is low.

These buffer distances are considered adequate to mitigate environmental and odour impacts.

6 Effluent system details

The effluent system will be constructed as simple two pond system consisting of the following:

- 0.7 ML Solids pond
- 5 ML Green water pond

Figure 5 Plan showing dairy shed and effluent ponds

6.1 Solids pond

The Toolkit design requires a minimum of 0.6 ML of effective volume based on an annual desludging, and the proposed design provides 0.7 ML of effective storage. The dimensions are $35 \times 15m$ assuming a depth of 4m and a 2:1 wall batter ratio.

Figure 6 Solids pond sizing calculation from the Effluent Toolkit

The solids pond will receive the raw effluent from the dairy shed washdown via a gravity pipeline. The solids pond will settle solids with liquid effluent decanting across via a T junction pipe (minimum 200mm diameter and extending 300mm below the pond surface) to the green water pond. This ensures the water is drawn from below the surface, preventing any solids crust on the surface from blocking the connection.

6.2 Green water storage dam

The Toolkit undertakes a simplistic assessment of storage volume by requiring storage for any month where 10th percentile rainfall is greater than 90th percentile ET.

This assessment calculates a minimum of 4.1 ML of effective storage required, and the proposed design provides for 5 ML of effective storage. The proposed pond shape is irregular and the volume has been confirmed via engineering design, however using the toolkit sizing tool it calculates an effective storage volume of 4.5ML

Figure 7 Green water pond sizing calculation from the Effluent Toolkit

6.3 Irrigation reuse system

The farm has 20ha under a pivot, and an additional 60 ha under soft and hard hose irrigators.

7 Effluent System Management

There are a number of steps involved in effective management of an effluent system to ensure that it performs as designed. Refer also to section 11 System maintenance.

7.1 Solids pond and application to pasture

- The solids pond must be desludged at least every year to ensure the design capacity of the pond is maintained. The sludge can directly applied to paddocks via a slurry spreader.
- If the sludge is to be stockpiled and dewatered, then the stockpile area should be constructed to have an impermeable base such as a clay lining, and be designed to drain all runoff to the effluent system.
- If desludging by vacuum tanker, ensure that the storage pond has effluent available to be pumped back for agitation when the slurry gets too thick to pump.
- A small volume of sludge should remain in the base of the pond to prevent cracking due to drying.
- The area around the pond should be kept free of weeds and excessive grass growth. Pond edges should be clearly visible and not obscured by vegetation.
- Application of solids to pasture should match soil fertility targets and be coordinated with nutrient budgeting, in order to prevent areas from receiving excessive nutrient loadings. In addition, application areas will avoid sensitive environments such as any drainage lines, native vegetation areas and property boundaries. Refer section 8 for more details.

7.2 Effluent Storage

- It is important to prioritise effluent irrigation during the summer irrigation period in order to reduce the dam volume prior to winter. If effluent irrigation must occur during winter, it should occur in consideration of the soil moisture level and weather forecast, to prevent effluent runoff from pasture that is at maximum capacity.
- Effluent will be of most benefit when applied to actively growing crops or pastures.
- Shandying into irrigation water is very effective and reduces the risk of nutrient overload. This is proposed in this instance.
- The area around the ponds should be kept free of weeds and excessive grass growth. Pond edges should be clearly visible and not obscured by vegetation.
- Ensure adequate fencing is in place to prevent stock accessing the trenches and pond.

7.3 Application System

- Ensure spray drift does not land beyond the property boundary.
- Ensure there is no runoff of green water from the target application area.
- Do not undertake irrigation if any of the ephemeral drainage lines in the irrigation areas are running, which will only occur directly after rainfall.

7.4 Grazing Management

• Soil test paddocks utilised for effluent disposal, to ensure nutrient levels are optimum for both plant and animal health. It is recommended that this is undertaken annually.

8 Nutrient management

Livestock effluent is a natural fertiliser and soil conditioner, and can be used to provide nutrients and organic matter to soils if used effectively. Effluent from storage should be applied to an area of pasture or crop sized to utilise the nutrients without adverse buildup.

The client is an agronomist and has advised that the total fertiliser requirements for irrigated pastures will be 360 kg/ha N, 60 kg/ha P and 100 kg/ha K.

Below are the calculations from the toolkit with a liquid application rate supplying half of the nutrient requirements and solids application rate providing all of the annual nutrient requirements. It demonstrates that there is sufficient area available at the site for effluent reuse, given the areas required are:

- 31.5 ha for liquid
- 2.2 ha for solid

Figure 8 Summary reuse area calculations from the effluent toolkit

9 OH&S requirements

It is the responsibility of the farm manager to identify any foreseeable hazards that may arise and that have the potential to harm the health and safety of anyone on the farm. Their principal duty is to take reasonable and practical steps to protect the health and safety of their employees and other farm visitors

Key issues in regard to health and safety and dairy effluent management are:

Ponds

Effluent ponds and trenches can be very deep, with steep internal walls. It may even be difficult to locate the edge of the pond due to excessive surface weed growth.

- Appropriate fencing and signage should be erected indicating potential hazards associated with the area.
- Effluent ponds represent a significant danger for tractors and other machinery due to the risk of the machine accidently falling into the pond. Any machinery work adjacent to or on the pond should be conducted under extreme caution.
- The pond should be machinery accessible on all sides if possible, and machinery anchor points installed at strategic locations reduce the possibility of machinery slipping into the ponds.
- Appropriate skill and training should be provided for all operators undertaking maintenance, de-sludging or nutrient sampling activities around the effluent system.
- If using a pontoon pump on the pond, ensure it is anchored in such a way that it can be dragged to the pond bank and made stable and safe for maintenance.

Other

- There is potential for the release of hazardous gases as a result of storage, pumping, mixing cleaning out and spreading of effluent, particularly in confined spaces. These gases can include hydrogen sulphide, carbon dioxide, ammonia and methane. As such all personnel should be trained and made aware of the risk of hazardous gases.
- Good personal hygiene practices are required to prevent possible transmission of diseases. This will be explained to all staff that may start work as part of their induction.
- Signage should be provided at major access points to the effluent irrigation area, stating "Warning Dairy Effluent Irrigation Area Do Not Drink"

10 Contingency planning

Contingency planning must occur to ensure appropriate responses to effluent system issues. The following outlines responses to key risks to the effluent system:

10.1 Pond wall breach or overflow

- Construct a temporary levy bank to contain the spill.
- Install a temporary spoon drain to direct uncontrolled overflows and seepage to a designated area away from waterways and lighter soil.
- Instigate a pond emptying procedure to lower existing volumes until walls can be reconstructed.
- Repair walls and banks by removing topsoil and vegetative growth before reconstructing the area with more clay or other impermeable material.
- Redirect effluent inflows from dairy shed and feedpads to other storage or irrigation systems until repairs are completed.

Note: If effluent enters a waterway or leaves the property boundary, the local council should be informed as soon as possible, but not later than 24 hours after the event, as required by the *Environmental Management and Pollution Control Act 1994*.

The appropriate contact number is as follows: **64 910 200**

10.2 Irrigator failure

- Maintain list of irrigation suppliers able to repair irrigation equipment
- Ensure storage dam level is maintained below the maximum at all times, to provide buffer storage if irrigation cannot occur for a period of time.
- Minimise facility water use (without compromising milk quality) to reduce wash down volumes entering the effluent stream.

11 System maintenance

Pond management:

- Inspect pond banks for signs of cracking or deterioration and instigate repairs.
- Inspect pond surroundings for wet areas which may indicate pond seepage.
- Annually check pond outlet pipes for seepage and replace damaged rubber seals.
- Check fencing around ponds is adequately tensioned and secured.
- Ensure yarding and storage surroundings are free of rubbish, foreign debris and plastic waste.

Pump maintenance:

- Ensure electrical wiring and switches on pumps are covered and serviced by qualified electricians.
- Ensure any pontoons on the pond have adequate buoyancy and are securely fixed to banks.
- Check waterproof switches for cracks.
- Listen to the pump while running for out-of-the-ordinary sounds and vibrations.
- Check bearings for excessive noise.
- Check bearings for excessive heat.
- Grease all grease-points every 6 months.
- Check belts are tight
- Check all belts or coupling covers are replaced and secured.
- Check all pump-securing bolts for corrosion and are tight.
- Check pump gland packing for excessive leaking, adjust or replace when needed.
- Check mechanical seal for leaking (if applicable).
- Check all pipe connections for integrity.
- Check area around electric motor and generator is clean and clear.
- Check for wear and tear of belts, pump and motor coupling, impeller, bowl and faceplate.

Conveyance pipes:

- Review joins and inspection points.
- Remove fibrous and solid build ups and ensure joints are secure.

• Ensure exposed conveyance pipes are protected from machinery and cattle.

Sumps and traps:

- Remove solids and sediment every few months.
- Use a rake or high pressure hose to clean weeping walls and screens and adjust spacing accordingly.
- Repair any damage to walls and screens.
- Remove fibrous build up from float switchers.
- Ensure fencing and railing around the sumps and traps are secure.

Irrigation equipment:

- Check all gearing, teeth and pawls for wear.
- Check cable connections.
- Check cable length for kinks or fraying.
- Check cable guide for wear.
- Check cams and cam followers for wear and ensure free running.
- Check nozzles and clear solid and fibrous build ups.

Slurry and solid spreaders:

- Ensure all guards and safety systems are in place on all machinery and equipment.
- Ensure farm implements are secured and mounted correctly to tractors.
- Thoroughly clean all equipment used to handle effluent before using it on other farms to reduce the likelihood of microbial transfer.
- Ensure all hydraulic and power take off drive systems are disengaged before undertaking repairs.
- Ensure spares parts are readily available, especially if effluent management is a direct application system which relies heavily on the operation of the slurry tanker.

Planning assessment memo

Date	24/10/2023
Project Title:	Cables dairy shed
Project number	P23040

Background

This planning report supports a planning application for a new dairy farm operation at Sheffield. It will be located at the existing Cables farm where a dairy operated previously. As such there is an existing site access, and water, power infrastructure for the new dairy.

The new dairy will be designed to best practice environmental and animal health standards.

The scope of the project is:

- Construct dairy shed and associated concrete yards
- Construct effluent treatment system consisting of solids pond and storage pond (approval via Division 4 dam permit and TDIA)
- Upgrade adjacent vehicle access and other ancillary works

The site details are as follows:

Project Address:	134 Cables Rd, Sheffield TAS 7306
Owners:	Joshua and Megan Cables
Property ID:	3484661
Title Reference:	54020/1

Planning assessment

The planning aspects of the site are as follows:

Zone:	Rural resource
Use:	Resource development (no permit required)
Overlays	Bushfire-prone areas

A response to the agriculture zone planning controls are as follows:

Use Standards

N/A, use is not discretionary

Development standards for buildings and works

26.4.2 location and configuration of development

Setbacks

- A1 The new dairy shed building meets the minimum required setback from boundaries.
- A2 The building height is 4.5m
- P3.1
 - The building elevation is at approx. 238.5m AHD while the hill behind is approx. 315m AHD, thus there is no visual impact to the skyline.
 - The building is adjacent existing small dams used as a water source for the dairy. However the presence of the dairy shed is unlikely to adversely impact the visual amenity of the dams as they are very minor water bodies not visible to the general public other than direct neighbouring properties.
 - The new shed roof and cladding will be low-reflectance metal sheeting.

Codes

Water and waterways code

E10.6.1

P1 A recognised waterway exists to the north of the proposed shed, which feeds the two adjacent ponds before discharging to the Don River to the east. This is a very minor waterway as it begins only 500m to the west of the ponds.

The proposed development, including the dairy shed, yards and effluent ponds have been designed to have negligible impacts to this existing waterway and in-stream ponds.

The dairy effluent will be contained to impervious surfaces, which all drain to the effluent ponds. The ponds have been designed and sized to not overtop for a 90th percentile rainfall and 10th percentile evapotranspiration year, as per the required Dairy Australia effluent design standards. The effluent ponds allow the liquid effluent to be beneficially reused at the property via irrigation to pasture. The ponds are sized to ensure adequate storage of effluent during the wetter winter months when effluent application is not suitable.

All works are outside of waterways so there will be no change to existing stream flows and ecological function. During construction a soil and water management plan will ensure that the risk of sediment runoff and erosion is mitigated.

Given the above the proposal represents a very low environmental risk to the adjacent waterway.
